

# EL9343

# Data Structure and Algorithm

Lecture 6: Hash Tables, Binary Search Tree

Instructor: Yong Liu

# The Search Problem

---

- ▶ Find items with keys matching a given search key
  - ▶ Given an array  $A$ , containing  $n$  keys, and a search key  $x$ , find the index  $i$  such as  $x=A[i]$
  - ▶ As in the case of sorting, a key could be part of a large record.

example of a record

<b>Key</b>	<b>other data</b>
------------	-------------------

# Special Case: Dictionaries

---

- ▶ **Dictionary:** Abstract Data Type (ADT) — maintain a set of items, each with a key, subject to
  - ▶ Insert(item): add item to set
  - ▶ Delete(item): remove item from set
  - ▶ Search(key): return item with key if it exists

# Applications

---

- ▶ Keeping track of customer account information at a bank
  - ▶ Search through records to check balances and perform transactions
- ▶ Search engine
  - ▶ Looks for all documents containing a given word
- ▶ ...

# Direct Addressing

---

- ▶ Assumptions:
  - ▶ Key values are distinct
  - ▶ Each key is drawn from a universe  $U = \{0, 1, \dots, m - 1\}$
- ▶ Idea:
  - ▶ Store the items in an array, indexed by keys
- ▶ **Direct-address table** representation:
  - ▶ An array  $T[0 \dots m - 1]$
  - ▶ Each **slot**, or position, in  $T$  corresponds to a key in  $U$
  - ▶ For an element  $x$  with key  $k$ , a pointer to  $x$  (or  $x$  itself) will be placed in location  $T[k]$
  - ▶ If there are no elements with key  $k$  in the set,  $T[k]$  is empty, represented by NIL

# Direct Addressing: Operations

*Alg.:* DIRECT-ADDRESS-SEARCH( $T, k$ )

**return**  $T[k]$

*Alg.:* DIRECT-ADDRESS-INSERT( $T, x$ )

$T[\text{key}[x]] \leftarrow x$

*Alg.:* DIRECT-ADDRESS-DELETE( $T, x$ )

$T[\text{key}[x]] \leftarrow \text{NIL}$

Running time for  
these operations:  $O(1)$

(insert/delete in  $O(1)$  time)

# Example

---

## Example 1:

- ▶ 100 records with distinct integer keys ranging from 1 to 100,
- ▶ create an array A of 100 items, store item with key  $i$  in  $A[i]$

## Example 2:

- ▶ keys are nine-digit social security numbers
- ▶ create an array A of  $10^9$  items to store 100 items!
- ▶ number of items much smaller than key value range

# Hash Tables

---

- ▶ When  $|K|$  is much smaller than  $|U|$ , a hash table requires much less space than a direct-address table
- ▶ Can reduce storage requirements to  $|K|$
- ▶ Can still get  $O(1)$  search time, but on the average case, not the worst case

# Hash Tables

---

- ▶ Idea

- ▶ Use a function  $h$  to compute the slot for each key
- ▶ Store the element in slot  $h(k)$

- ▶ A hash function  $h$  transforms a key into an index in a hash table  $T[0 \dots m-1]$

$$h : U \rightarrow \{0, 1, \dots, m - 1\}$$

- ▶ We say that  $k$  hashes to slot  $h(k)$

- ▶ Advantages

- ▶ Reduce the range of array indices handled:  $m$  instead of  $|U|$
- ▶ Storage is also reduced

# Hash Tables: Example

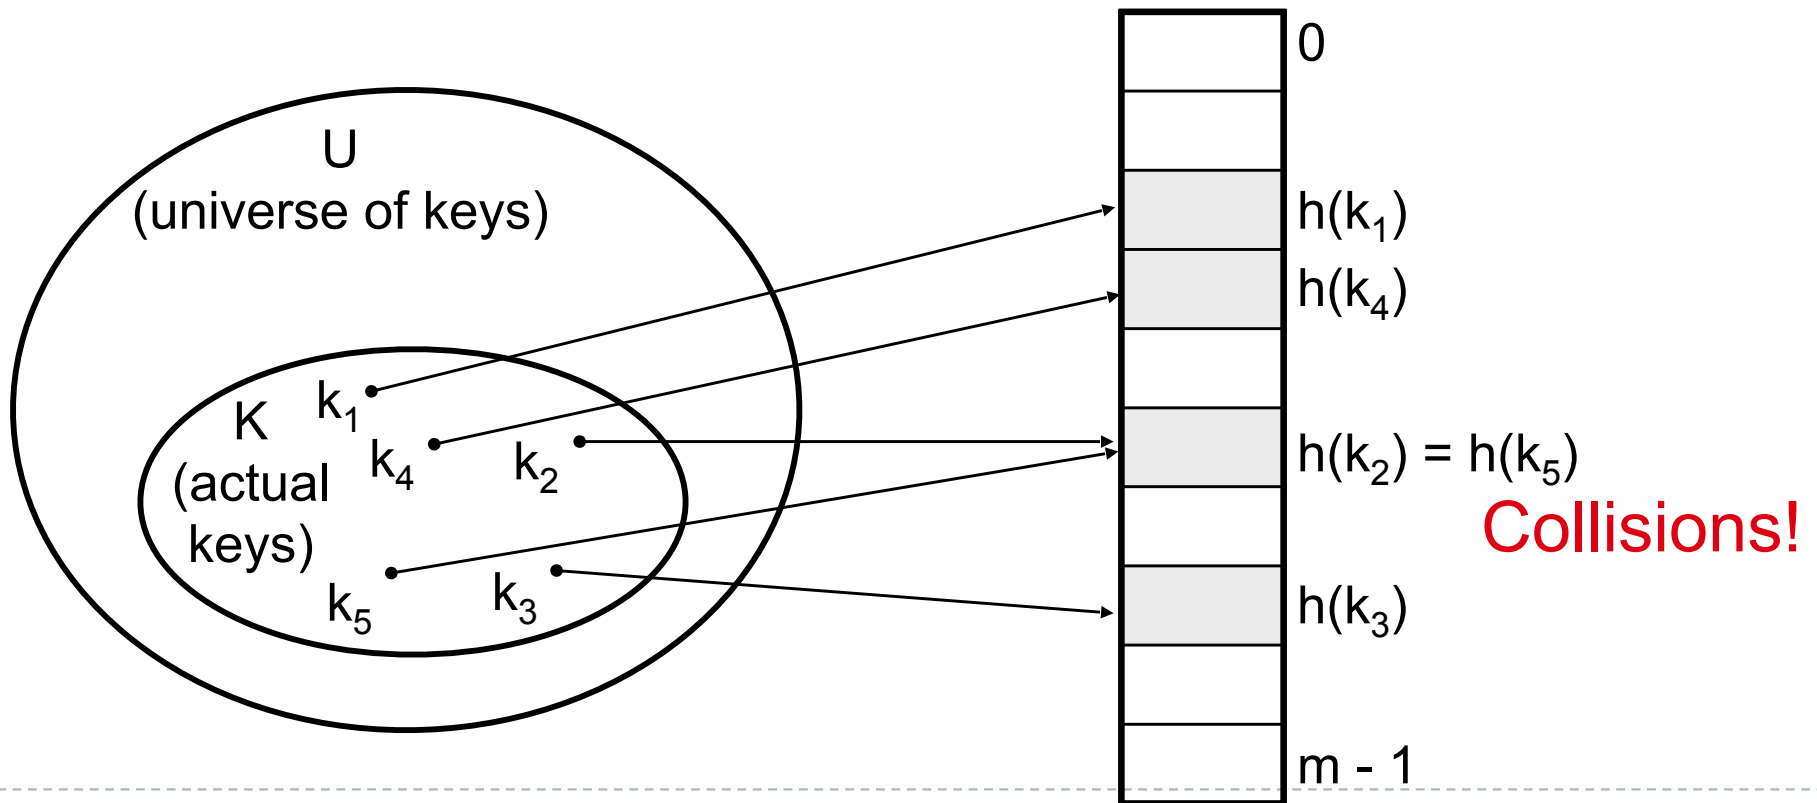

# Revisit Example 2

Suppose keys are 9-digit social security numbers

Possible Hash Functions

$h(\text{ssn}) = \text{ssn} \bmod 100$  (last 2 digits of ssn)

$h(103-224-511) = 11 = h(201-789-611)$

# Collisions

---

- ▶ Two or more keys hash to the same slot!!
- ▶ For a given set  $K$  of keys
  - ▶ If  $|K| \leq m$ , collisions may or may not happen, depending on the hash function
  - ▶ If  $|K| > m$ , collisions will definitely happen (i.e., there must be at least two keys that have the same hash value)
- ▶ Avoiding collisions completely is hard, even with a good hash function

# Handling Collisions

---

- ▶ We will review the following methods:
  - ▶ Chaining
  - ▶ Open addressing
    - ▶ Linear probing
    - ▶ Quadratic probing
    - ▶ Double hashing
- ▶ We will discuss chaining first, and ways to build “good” hash functions.

# Handling Collisions Using Chaining

## ► Idea

- Put all elements that hash to the same slot into a linked list

- Slot  $j$  contains a pointer to the head of the list of all elements that hash to  $j$

# Collision with Chaining - Discussion

---

- ▶ Choosing the size of the table
  - ▶ Small enough not to waste space
  - ▶ Large enough such that lists remain short
  - ▶ Typically  $1/5$  or  $1/10$  of the total number of elements
- ▶ How should we keep the lists: ordered or not?
  - ▶ Not ordered!
    - ▶ Insert is fast
    - ▶ Can easily remove the most recently inserted elements

# Insertion in Hash Tables

---

*Alg.:* CHAINED-HASH-INSERT( $T, x$ )

insert  $x$  at the head of list  $T[h(\text{key}[x])]$

- ▶ Worst-case running time is  $O(1)$
- ▶ Assumes that the element being inserted isn't already in the list
- ▶ It would take an additional search to check if it was already inserted

# Deletion in Hash Tables

---

*Alg.:* CHAINED-HASH-DELETE( $T, x$ )

delete  $x$  from the list  $T[h(\text{key}[x])]$

- ▶ Need to find the element to be deleted.
- ▶ Worst-case running time:
  - ▶ Deletion depends on searching the corresponding list

# Searching in Hash Tables

---

*Alg.:* CHAINED-HASH-SEARCH( $T, k$ )

search for an element with key  $k$  in list  $T[h(k)]$

- ▶ Running time is proportional to the length of the list of elements in slot  $h(k)$

# Analysis of Hashing with Chaining: Worst Case

- ▶ How long does it take to search for an element with a given key?
- ▶ Worst case:
  - ▶ All  $n$  keys hash to the same slot
  - ▶ Worst-case time to search is  $\Theta(n)$ , plus time to compute the hash function

# Analysis of Hashing with Chaining: Average Case

- ▶ Average case
  - ▶ depends on how well the hash function distributes the  $n$  keys among the  $m$  slots
- ▶ Simple uniform hashing assumption
  - ▶ Any given element is equally likely to hash into any of the  $m$  slots (i.e., probability of collision  $\Pr(h(x)=h(y))$ , is  $1/m$ )
- ▶ Length of a list:  $T[j] = n_j, j = 0, 1, \dots, m - 1$
- ▶ Number of keys in the table:  $n = n_0 + n_1 + \dots + n_{m-1}$
- ▶ Average value of  $n_j$ :  $E[n_j] = \alpha = n/m$

# Load Factor of a Hash Table

- ▶ Load factor of a hash table T:

$$\alpha = n/m$$

- ▶  $n$  = # of elements stored in the table
  - ▶  $m$  = # of slots in the table = # of linked lists
- ▶  $\alpha$  encodes the average number of elements stored in a chain
- ▶  $\alpha$  can be  $<$ ,  $=$ ,  $> 1$

## Case 1: Unsuccessful Search (i.e., item not stored in the table)

---

### Theorem

- ▶ An unsuccessful search in a hash table takes expected time  $\Theta(1 + \alpha)$  under the assumption of simple uniform hashing (i.e., probability of collision  $\Pr(h(x)=h(y))$ , is  $1/m$ )

### Proof

- ▶ Searching unsuccessfully for any key  $k$ 
  - ▶ need to search to the end of the list  $T[h(k)]$
- ▶ Expected length of the list:
  - ▶  $E[n_{h(k)}] = \alpha = n/m$
- ▶ Expected number of elements examined in an unsuccessful search is  $\alpha$
- ▶ Total time required is:
  - ▶  $O(1)$  (for computing the hash function) +  $\alpha \longrightarrow \Theta(1 + \alpha)$

# Case 2: Successful Search

## Theorem

- ▶ An successful search in a hash table takes expected time  $\Theta(1 + \alpha)$  under the assumption of simple uniform hashing

**Proof:** let  $x_i$  be the  $i$ -th element inserted to the hash table, define  $X_{ij}$  to be the indicator random variable that element  $i$  and  $j$  will be hashed to the same value, then the expected number of elements examined in a successful search is:

$$\begin{aligned} E \left[ \frac{1}{n} \sum_{i=1}^n \left( 1 + \sum_{j=i+1}^n X_{ij} \right) \right] \\ = \frac{1}{n} \sum_{i=1}^n \left( 1 + \sum_{j=i+1}^n E[X_{ij}] \right) &= 1 + \frac{n-1}{2m} \\ &= 1 + \frac{\alpha}{2} - \frac{\alpha}{2n} . \end{aligned}$$

# Analysis of Search in Hash Table

---

- ▶ If  $m$  (# of slots) is proportional to  $n$  (# of elements in the table):
  - ▶  $n = O(m)$
  - ▶  $\alpha = n/m = O(m)/m = O(1)$
- ▶ Searching takes constant time on average

# Hash Functions

---

- ▶ A hash function transforms a key into a table address
- ▶ What makes a good hash function?
  - ▶ Easy to compute
  - ▶ Approximates a random function: for every input, every output is equally likely (simple uniform hashing)
- ▶ In practice, it is very hard to satisfy the simple uniform hashing property
  - ▶ i.e., we don't know in advance the probability distribution that keys are drawn from

# Good Approaches for Hash Functions

---

- ▶ Minimize the chance that closely related keys hash to the same slot
  - ▶ Strings such as pt and pts should hash to different slots
- ▶ Derive a hash value that is independent from any patterns that may exist in the distribution of the keys

# The Division Method

---

- ▶ Idea

- ▶ Map a key  $k$  into one of the  $m$  slots by taking the remainder of  $k$  divided by  $m$

$$h(k) = k \bmod m$$

- ▶ Advantage

- ▶ Fast, requires only one operation

- ▶ Disadvantage

- ▶ Certain values of  $m$  are bad, e.g.,
    - ▶ power of 2
    - ▶ non-prime numbers

# The Division Method: Example

- ▶ If  $m = 2^p$ , then  $h(k)$  is just the least significant  $p$  bits of  $k$

- ▶  $p = 1 \Rightarrow m = 2$

$\Rightarrow h(k) = \{0, 1\}$ , least significant 1 bit of  $k$

- ▶  $p = 2 \Rightarrow m = 4$

$\Rightarrow h(k) = \{0, 1, 2, 3\}$ , least significant 2 bits of  $k$

- ▶ Choose  $m$  to be a prime, not close to a power of 2

- ▶ Column 2:  $k \bmod 97$

- ▶ Column 3:  $k \bmod 100$

16838	57	38
5758	35	58
10113	25	13
17515	55	15
31051	11	51
5627	1	27
23010	21	10
7419	47	19
16212	13	12
4086	12	86
2749	33	49
12767	60	67
9084	63	84
12060	32	60
32225	21	25
17543	83	43
25089	63	89
21183	37	83

20495	28	95
10311	29	11
11367	18	67

# The Multiplication Method

---

## Idea

- ▶ Multiply key  $k$  by a constant  $A$ , where  $0 < A < 1$
- ▶ Extract the fractional part of  $kA$
- ▶ Multiply the fractional part by  $m$
- ▶ Take the floor of the result

$$h(k) = \lfloor m(kA - \lfloor kA \rfloor) \rfloor = \lfloor m \underbrace{(kA \bmod 1)}_{\text{fractional part of } kA} \rfloor$$

fractional part of  $kA = kA - \lfloor kA \rfloor$

- ▶ **Disadvantage:** Slower than division method
- ▶ **Advantage:** Value of  $m$  is not critical, e.g., typically  $2^p$

# The Multiplication Method: Example

---

- The value of  $m$  is not critical now (e.g.,  $m = 2^p$ )

assume  $m = 2^3$

$$\begin{array}{r} .101101 \text{ (A)} \\ 110101 \text{ (k)} \\ \hline 1001010.0110011 \text{ (kA)} \end{array}$$

discard: 1001010

shift .0110011 by 3 bits to the left

011.0011

take integer part: 011

thus,  $h(110101)=011$

# Universal Hashing

---

- ▶ In practice, keys are not randomly distributed
- ▶ Any fixed hash function, adversary may construct a key sequence so that the search time is  $\Theta(n)$
- ▶ Goal: hash functions that produce random table indices irrespective of the keys
- ▶ Idea: select a hash function at random, from a designed class of functions at the beginning of the execution

# Universal Hashing

---

# Definition of Universal Hash Functions

---

From the textbook:

Let  $\mathcal{H}$  be a finite collection of hash functions that map a given universe  $U$  of keys into the range  $\{0, 1, \dots, m - 1\}$ . Such a collection is said to be *universal* if for each pair of distinct keys  $k, l \in U$ , the number of hash functions  $h \in \mathcal{H}$  for which  $h(k) = h(l)$  is at most  $|\mathcal{H}|/m$ . In other words, with a hash function randomly chosen from  $\mathcal{H}$ , the chance of a collision between distinct keys  $k$  and  $l$  is no more than the chance  $1/m$  of a collision if  $h(k)$  and  $h(l)$  were randomly and independently chosen from the set  $\{0, 1, \dots, m - 1\}$ .

# Universal Hashing: Main Result

---

- ▶ With universal hashing the chance of collision between distinct keys  $k$  and  $l$  is no more than the chance  $1/m$  of a collision if locations  $h(k)$  and  $h(l)$  were randomly and independently chosen from the set  $\{0, 1, \dots, m - 1\}$

# Designing a Universal Class of Hash Functions

- ▶ Choose a prime number  $p$  large enough so that every possible key  $k$  is in the range  $[0 \dots p - 1]$

$$Z_p = \{0, 1, \dots, p - 1\} \text{ and } Z_p^* = \{1, \dots, p - 1\}$$

- ▶ Define the following hash function

$$h_{a,b}(k) = ((ak + b) \bmod p) \bmod m,$$

$$\forall a \in Z_p^* \text{ and } b \in Z_p$$

- ▶ The family of all such hash functions is

$$H_{p,m} = \{h_{a,b} : a \in Z_p^* \text{ and } b \in Z_p\}$$

The class  $H_{p,m}$  of hash functions is universal

$a, b$ : chosen randomly at the beginning of execution

# Universal Hashing Function: Example

---

*E.g.:*  $p = 17$ ,  $m = 6$

$$h_{a,b}(k) = ((ak + b) \bmod p) \bmod m$$

$$h_{3,4}(8) = ((3 \cdot 8 + 4) \bmod 17) \bmod 6$$

$$= (28 \bmod 17) \bmod 6$$

$$= 11 \bmod 6$$

$$= 5$$

# Universal Hashing Function: Advantages

---

- ▶ Universal hashing provides good results on average performance, independently of the keys to be stored
- ▶ Guarantees that no input will always elicit the worst-case performance
- ▶ Poor performance occurs only when the random choice returns an inefficient hash function – this has small probability

# Binary Search Tree Property

---

- ▶ Binary search tree property:
  - ▶ If  $y$  is in left subtree of  $x$ ,
    - ▶ then  $\text{key}[y] \leq \text{key}[x]$
  - ▶ If  $y$  is in right subtree of  $x$ ,
    - ▶ then  $\text{key}[y] \geq \text{key}[x]$

$$\text{key}[\text{leftSubtree}(x)] \leq \text{key}[x] \leq \text{key}[\text{rightSubtree}(x)]$$

# Traversing a Binary Search Tree

- ▶ **Inorder** tree walk:

- ▶ Root is printed between the values of its left and right subtrees: left, root, right
- ▶ Keys are printed in **sorted** order

- ▶ **Preorder** tree walk:

- ▶ root printed first: root, left, right

- ▶ **Postorder** tree walk:

- ▶ root printed last: left, right, root

Inorder: 2 3 5 5 7 9

Preorder: 5 3 2 5 7 9

Postorder: 2 5 3 9 7 5

# Inorder tree walk

---

*Alg:* INORDER-TREE-WALK( $x$ )

1. **if**  $x \neq \text{NIL}$
2.     INORDER-TREE-WALK ( left [ $x$ ] )
3.     print key [ $x$ ]
4.     INORDER-TREE-WALK ( right [ $x$ ] )

*E.g.:*

Output: 2 3 5 5 7 9

► Running time:

- $\Theta(n)$ , where  $n$  is the size of the tree rooted at  $x$

# Binary Search Trees

---

- ▶ Support many operations
  - ▶ SEARCH, MINIMUM, MAXIMUM, PREDECESSOR, SUCCESSOR, INSERT, DELETE
- ▶ Running time of basic operations on binary search trees
  - ▶ On average:  $\Theta(\log n)$ 
    - ▶ The expected height of the tree is  $\log n$
  - ▶ In the worst case:  $\Theta(n)$ 
    - ▶ The tree is a linear chain of  $n$  nodes (very unbalanced)

# Searching for a Key

---

- ▶ Given a pointer to the root of a tree and a key  $k$ :

- ▶ Return a pointer to a node with key  $k$  if one exists
- ▶ Otherwise return NIL

- ▶ Idea

- ▶ Starting at the root: trace down a path by comparing  $k$  with the key of the current node:
  - ▶ If the keys are equal: we have found the key
  - ▶ If  $k < \text{key}[x]$  search in the left subtree of  $x$
  - ▶ If  $k > \text{key}[x]$  search in the right subtree of  $x$

# Searching for a Key: Example

---

- Search for key 13:
  - 15 → 6 → 7 → 13

# Binary Search Trees

---

*Alg:* TREE-SEARCH( $x, k$ )

1. **if**  $x = \text{NIL}$  or  $k = \text{key}[x]$
2.     **then return**  $x$
3. **if**  $k < \text{key}[x]$
4.     **then return** TREE-SEARCH(left  $[x], k$  )
5.     **else return** TREE-SEARCH(right  $[x], k$  )

Running Time:  $O(h)$ ,  
 $h$  – the height of the tree

# Binary Search Trees: Finding the Minimum

- ▶ Goal: find the **minimum** value in a BST
  - ▶ Following **left** child pointers from the root, until a NIL is encountered

*Alg:* TREE-MINIMUM(x)

**while** left [x]  $\neq$  NIL

**do**  $x \leftarrow$  left [x]

**return** x

Minimum = 2

- ▶ Running time:  $O(h)$ ,  $h$  – height of tree

# Binary Search Trees: Finding the Maximum

- ▶ Goal: find the **maximum** value in a BST
  - ▶ Following **right** child pointers from the root, until a NIL is encountered

*Alg:* TREE-MAXIMUM(x)

```
while right [x]  $\neq$  NIL  
    do x  $\leftarrow$  right [x]  
return x
```

Maximum = 20

- ▶ Running time:  $O(h)$ ,  $h$  – height of tree

# Successor

- ▶ *Def: successor* ( $x$ ) =  $y$ , such that key [ $y$ ] is the smallest key  $>$  key [ $x$ ]

*E.g.: successor* (15) = 17

*successor* (13) = 15

*successor* (9) = 13

- ▶ **Case 1: right ( $x$ ) is non empty**

- ▶ *successor* ( $x$ ) = the minimum in right ( $x$ )

- ▶ **Case 2: right ( $x$ ) is empty**

- ▶ go up the tree until the current node is a left child:  
*successor* ( $x$ ) is the parent of the current node

- ▶ if you cannot go further (and you reached the root):  $x$  is the largest element

# Finding the Successor

*Alg:* TREE-SUCCESSOR( $x$ )

1. **if** right [ $x$ ]  $\neq$  NIL
2.     **then return** TREE-MINIMUM(right [ $x$ ])
3.  $y \leftarrow p[x]$
4. **while**  $y \neq$  NIL and  $x =$  right [ $y$ ]
5.     **do**  $x \leftarrow y$
6.      $y \leftarrow p[y]$
7. **return**  $y$

Running time:  $O(h)$ ,  $h$  – height of the tree

# Predecessor

*Def: predecessor (x) = y, such that key [y] is the biggest key < key [x]*

*E.g.: predecessor (15) = 13*

*predecessor (9) = 7*

*predecessor (7) = 6*

## Case 1: left (x) is non empty

*predecessor (x) = the maximum in left (x)*

## Case 2: left (x) is empty

- ▶ go up the tree until the current node is a right child:  
*predecessor (x)* is the parent of the current node
- ▶ if you cannot go further (and you reached the root): x is the smallest element

# Insertion

- ▶ Goal:
  - ▶ Insert value  $v$  into a binary search tree
- ▶ Idea:
  - ▶ If  $\text{key}[x] < v$  move to the right child of  $x$ , else move to the left child of  $x$
  - ▶ When  $x$  is NIL, we found the correct position
  - ▶ If  $v < \text{key}[y]$  insert the new node as  $y$ 's left child else insert it as  $y$ 's right child
  - ▶ Beginning at the root, go down the tree and maintain:
    - ▶ Pointer  $x$  : traces the downward path (current node)
    - ▶ Pointer  $y$  : parent of  $x$  ("trailing pointer" )

# Insertion: Example

Insert 13:

$x = \text{NIL}$   
 $y = 15$

# Tree Insertion

1.  $y \leftarrow \text{NIL}$
2.  $x \leftarrow \text{root}[T]$
3. **while**  $x \neq \text{NIL}$
4.     **do**  $y \leftarrow x$
5.         **if**  $\text{key}[z] < \text{key}[x]$
6.             **then**  $x \leftarrow \text{left}[x]$
7.             **else**  $x \leftarrow \text{right}[x]$
8.  $p[z] \leftarrow y$
9. **if**  $y = \text{NIL}$
10.     **then**  $\text{root}[T] \leftarrow z$  // Tree T was empty
11.     **else if**  $\text{key}[z] < \text{key}[y]$
12.         **then**  $\text{left}[y] \leftarrow z$
13.         **else**  $\text{right}[y] \leftarrow z$

Running time:  $O(h)$

# Deletion

- ▶ Goal:
  - ▶ Delete a given node  $z$  from a binary search tree
- ▶ Idea:
  - ▶ Case 1:  $z$  has no children
    - ▶ Delete  $z$  by making the parent of  $z$  point to NIL

# Deletion

- ▶ Case 2: z has one child
  - ▶ Delete z by making the parent of z point to z's child, instead of to z

# Deletion

## ▶ Case 3: z has two child

- ▶ z's successor (y) is the minimum node in z's right subtree
- ▶ y has either no children or one right child (but no left child)
- ▶ Delete y from the tree (via Case 1 or 2)
- ▶ Replace z's key and satellite data with y's.

# Binary Search Trees: Summary

---

- ▶ Operations on binary search trees:
  - ▶ SEARCH  $O(h)$
  - ▶ PREDECESSOR  $O(h)$
  - ▶ SUCCESSION  $O(h)$
  - ▶ MINIMUM  $O(h)$
  - ▶ MAXIMUM  $O(h)$
  - ▶ INSERT  $O(h)$
  - ▶ DELETE  $O(h)$
- ▶ These operations are fast if the height of the tree is small

# What's next...

---

- ▶ Binary Search Trees (Cont.d)
- ▶ Midterm Review
